Copper has 20 orbiting electrons with only one electron in the outermost shell. The fact that the outermost shell with its 29th electron is incomplete subshell can contain 2 electrons and distant from the nucleus reveals that this electron is loosely bound to its parent atom. The application of an external electric field of the correct polarity can easily draw this loosely bound electron from its atomic structure for conduction. Both intrinsic silicon and germanium have complete outer shells due to the sharing covalent bonding of electrons between atoms. Electrons that are part of a complete shell structure require increased levels of applied attractive forces to be removed from their parent atom. 2. Intrinsic material an intrinsic semiconductor is one that has been refined to be as pure as physically possible. That is, one with the fewest possible number of impurities. Negative temperature coefficient materials with negative

temperature coefficients have decreasing resistance levels as the temperature increases. The majority carrier is the electron while the minority carrier is the hole. The majority carrier is the hole while the minority carrier is the electron. 8. A donor atom has five electrons in its outermost valence shell while an acceptor atom has only 3 electrons in the valence shell. 19. Majority carriers are those carriers of a material that far exceed the number of any other carriers in the material. Ge typically has a working limit of about 85 degrees centigrade while Si can be used at temperatures approaching 200 degrees centigrade. Silicon diodes also have a higher current handling capability.

Usually, however, technology only permits a close replica of the desired characteristics. The "ideal" characteristics provide an excellent basis for comparison with the actual device characteristics permitting an estimate of how well the device or system will perform. On occasion, the "ideal" device or system can be assumed to obtain a good estimate of the overall response of the design. The transition capacitance is due to the depletion region acting like a dielectric in the reverse bias region, while the diffusion capacitance is determined by the rate of charge injection into the region just outside the depletion boundaries of a forward biased device. The Si diode with 5 V at the cathode is "on" while the other is "off". Therefore assume lower diode "on" and upper diode "off". Therefore, with 5 V at both input terminals, assume Si diode "off" and Ge diode "on". The maximum level of  $I_R$ s will in turn determine the maximum permissible level of  $V_i$ .
